In computer science, best, worst, and average cases of a given algorithm express what the resource usage is at least, at most and on average, respectively. Usually the resource being considered is running time, i.e. time complexity, but it could also be memory or other resource. Best case is the function which performs the minimum number of ...

Worst-case and average-case analysis In our analysis of insertion sort, we looked at both the best case, in which the input array was already sorted, and the worst case, in which the input array was reverse sorted. For the remainder of this book, though, we shall usually concentrate on.

Another, more complex example is quicksort: Its average and best running time for random data is proportional to  $n \cdot \log n$ . The worst case time is still  $n \cdot n$  (often for an already sorted input, but this depends on the algorithm to find the pivot element in the divide step).
